Abstract
Background and objectives: Laparoscopic surgery has become a popular surgical tool when compared to traditional open surgery. There are limited data on pediatric patients regarding whether pneumoperitoneum affects cerebral oxygenation although end-tidal CO2 concentration remains normal. Therefore, this study was designed to evaluate the changes of cerebral oxygen saturation using near-infrared spectroscopy during laparoscopic surgery in children.
Methods: The study comprised forty children who were scheduled for laparoscopic (Group L, n = 20) or open (Group O, n = 20) appendectomy. Hemodynamic variables, right and left regional cerebral oxygen saturation (RrSO2 and LrSO2), fraction of inspired oxygen, end-tidal carbon dioxide pressure (PETCO2), peak inspiratory pressure (Ppeak), respiratory minute volume, inspiratory and end-tidal concentrations of sevoflurane and body temperature were recorded. All parameters were recorded after anesthesia induction and before start of surgery (T0, baseline), 15 min after start of surgery (T1), 30 min after start of surgery (T2), 45 min after start of surgery (T3), 60 min after start of surgery (T4) and end of the surgery (T5).
Results: There were progressive decreases in both RrSO2 and LrSO2 levels in both groups, which were not statistically significant at T1, T2, T3, T4. The RrSO2 levels of Group L at T5 were significantly lower than that of Group O. One patient in Group L had an rSO2 value <80% of the baseline value.
Conclusions: Carbon dioxide insufflation during pneumoperitoneum in pediatric patients may not affect cerebral oxygenation under laparoscopic surgery.

Introduction

Laparoscopic surgery has become a popular surgical tool due to its less invasive nature, thereby providing a more rapid recovery with a shorter hospital stay, decreased postoperative pain and improved cosmetic outcome when compared to traditional open surgery.\(^1\)\(^2\) The successful application of laparoscopic techniques in adults has led to their increasing use in pediatric surgery.\(^3\)\(^4\) An investigation in adult patients has shown that although relatively uncommon, significant changes in cerebral oxygenation occur in some patients during CO\(_2\) insufflation for laparoscopic surgery.\(^5\)\(^6\) There are limited data on pediatric patients regarding whether pneumoperitoneum affects cerebral oxygenation although end-tidal CO\(_2\) concentration remains normal.

Our hypothesis was that cerebral oxygen saturation would decrease in pediatric patients during laparoscopic surgery because of pneumoperitoneum and CO\(_2\) absorption. Therefore, this study was designed to evaluate the changes of cerebral oxygen saturation using near-infrared spectroscopy (NIRS) during laparoscopic surgery in children.

Methods

After receiving approval from the ethics committee of the Kırıkkale University, forty children with ASA physical status I who were scheduled for laparoscopic (Group L, \(n = 20\)) or open (Group O, \(n = 20\)) appendectomy surgery were enrolled in this prospective study. Written informed consent was obtained from all the patients’ parents before the surgery. Exclusion criteria were as follows: patients whose parents did not give consent, ASA II and above, age \(\geq 18\) and \(\leq 2\) years.

The children’s ages, weights and heights were noted. All patients were monitored by electrocardiogram (ECG), non-invasive blood pressure (BP), heart rate (HR), peripheral oxygen saturation (Sp\(_{O_2}\)), right and left regional cerebral oxygen saturation (RrSO\(_2\) and LrSO\(_2\)), fraction of inspired oxygen, end-tidal carbon dioxide pressure (PETCO\(_2\)), peak inspiratory pressure (Ppeak), respiratory minute volume, inspiratory and end-tidal concentrations of sevoflurane and body temperature continuously throughout the anesthesia. In all patients for RrSO\(_2\) and LrSO\(_2\) measurement, sensors for cerebral oximeter (NIRS model INVOS 5100; Somanetics, Troy, MI) were placed bilaterally at least 2 cm above the eyebrow on the right and left sides of the forehead according to the manufacturer’s instructions before induction of anesthesia. Cerebral oxygen desaturation was defined as an rSO\(_2\) value <80% of the baseline value. In the event of such a decrease in rSO\(_2\), 100% oxygen was administered.

All children received a standardized anesthetic technique. Anesthesia was induced with intravenous thiopental (5 mg/kg\(^{-1}\)), remifentanil (0.2 \(\mu\)g/kg/min) and atracurium besilat (0.5 mg/kg). When maximum neuromuscular blocking effect was achieved, the same anesthesiologist performed
endotracheal intubation. Anesthesia was maintained with a minimum alveolar anesthetic concentration (MAC) of sevoflurane of 1% and 66% air in oxygen. A remifentanil infusion (0.05–0.2 μg/kg/min) was continued to maintain surgical analgesia. Mechanical ventilation was performed using a pressure-controlled mode (A53; Datex-Engstrom, Helsinki, Finland). Respiratory rate was adjusted to keep $P_{ETCO2}$ value between 35 and 45 mmHg throughout the surgery in both groups. In both groups, all patients were arranged in supine position throughout the surgery and during laparoscopic procedures; the abdominal pressure was maintained at 8–12 mmHg. At the end of the surgery, the neuromuscular block was reversed with neostigmine and atropine.

All parameters were recorded after anesthesia induction and before start of surgery (T0, baseline), 15 min after start of surgery (T1), 30 min after start of surgery (T2), 45 min after start of surgery (T3), 60 min after start of surgery (T4) and end of the surgery (T5). The duration of the anesthesia and the surgery were also recorded.

### Statistical analysis

Data were analyzed using the IBM SPSS (version 15.0 for Windows) statistical package. Data were expressed as mean ± standard deviation (SD) or n where appropriate. The Mann–Whitney U test was employed for the comparison of continuous variables among groups. A $p$-value of less than 0.05 was accepted as statistically significant.

### Results

The two groups were similar with respect to their demographic data (Table 1).

The duration of both the anesthesia and the procedure were also comparable between the groups (Table 1).

The hemodynamic parameters such as HR mean arterial BP, SpO2 and $P_{ETCO2}$ levels were comparable between the groups (Table 2).

The change in rSO2 is shown in Table 3. Although there was a progressive decrease in both rRsO2 and LrSO2 levels in both groups, it was not statistically significant at T1, T2, T3, T4 ($p > 0.05$). The rRsO2 levels of Group L at T5 were significantly lower than that of Group O ($p = 0.032$).

Only one patient in Group L had an rSO2 value <80% of the baseline value.

### Discussion

The main finding of this study is that CO2 insufflation during pneumoperitoneum in pediatric patients may not affect cerebral oxygenation under laparoscopic surgery.

Pneumoperitoneum exerts its effects on organ systems primarily via the physical pressure on those systems and secondly due to the systemic absorption of carbon dioxide (the diffusion of CO2 across the peritoneum and into the bloodstream). The physiological effects are increased with decreasing age and weight due to decreased muscle bulk, an increased peritoneal surface area to mass ratio, decreased peritoneal thickness and decreased organ-specific reserve.

Intra-abdominal pressure (IAP) is a critical determinant of cardiovascular stability during laparoscopy. Raised IAP during pneumoperitoneum determines bradycardia or asystole because of a high level of vagal tone in children. To keep the physiological changes to a minimum, the lowest IAP required to carry out the procedure safely is recommended as less than 15 mmHg in children. Insufflation with an IAP <10 mmHg augments preload through the displacement of blood from the splanchnic vasculature, while pressures of >15 mmHg impedes venous return. According to these recommendations, we keep IAP between 8 and 10 mmHg during laparoscopic surgery.

Cerebral oximetry has been extensively evaluated in adults as well as in pediatric surgery and neonatology. Cerebral oximetry with near-infrared spectroscopy (NIRS) allows continuous and non-invasive monitoring of rSO2, which reflects a balance between cerebral oxygen supply and demand. NIRS quantitates a venous-weighted ratio of oxygenated and deoxygenated hemoglobin in the region of the cerebral cortex underlying the sensors, which are usually placed on the forehead. An rSO2 value <80% of the baseline or rSO2 <50% were associated with a higher incidence of cerebral ischemia, postoperative cognitive dysfunction and longer hospital stays. Additionally, if the baseline is lower than 50%, the critical threshold should be reduced to 15%. In the present study, one patient had an rSO2 value <80% of the baseline at the fortieth min of surgery during pneumoperitoneum.

There are a limited number of studies focusing on the relationship between laparoscopic surgery and rSO2 in pediatrics. De Waal et al. demonstrated that insufflation of CO2 at low IAPs (≤8 mmHg) in children causes considerable increases in $P_{ETCO2}$ and arterial CO2 pressure (PaCO2) that are reflected in increased in rSO2 and cerebral blood volume, even when superimposed on a baseline of mild hypocapnia.

Data are mean ± SD or n.
To, baseline, after anesthesia induction, before start of surgery; T1, 15 min after start of surgery; T2, 30 min after start of surgery; T3, 45 min after start of surgery; T4, 60 min after start of surgery; T5, end of the surgery; HR, heart rate; MAP, mean arterial pressure; SpO2, peripheral oxygen saturation; PETCO2, end-tidal carbon dioxide pressure.

In contrast, Tsypin et al. reported an average of a 3% reduction in regional cerebral tissue saturation in children during gynecological laparoscopic interventions, which was measured by the Critikon RedOx Monitor 2020 device. According to our results, we found no difference in reduction of rSO2 between laparoscopy and open surgery.

The limitation of the current study is that we did not monitor PaCO2 changes during CO2 insufflation. It was reported that PETCO2 may not correlate with PaCO2, therefore arterial blood gas analysis monitoring should be performed during long laparoscopic procedures. Because of laparoscopic appendectomy is a minimal invasive surgery, so that PaCO2 monitoring may not be appropriate ethically.

In conclusion, the results of the present study showed that all patients, except one from the laparoscopic group, tolerated CO2 insufflation without significant affects on cerebral oxygenation. Although cerebral rSO2 changes are insignificant and there is no standard care for the use of NIRS-based cerebral oximetry in pediatric anesthesia, the INVOS cerebral oximeter may be a helpful monitoring tool for detecting real-time rSO2 changes during pneumoperitoneum with CO2.
